BrainGrow

Code Review Verification — Post-Fix Confirmation Checklist

Version 1.0 | March 2026 | Vektas Solutions

Author: Matthew Monroe

---

1. Purpose

A prior code review identified seven concerns in the BrainGrow codebase. Fixes have been applied. This document instructs Copilot to perform a systematic verification pass — confirming each fix is correctly implemented, complete, and has not introduced secondary issues.

For each item, Copilot should: locate the relevant code, verify the fix matches the specification below, run or reason through edge cases, and report the result as CONFIRMED, PARTIAL, or UNRESOLVED with explanation.

> *Do not assume a fix is correct because it was attempted. Verify each item independently against the specific acceptance criteria listed in this document.*

---

2. Verification Summary Table

Complete this table as each item is verified. Report results back to the user.

Issue	Fix Applied	Status
`DenseModel rebuild`	Encode once, append incrementally	[ ]
`assign_slot O(n) scan`	dormant_queue O(1) pop	[ ]
`Thread safety`	RLock on all VectorSpace mutations	[ ]
`Boundary violation heuristic`	negative_domains set registry	[ ]
`ingest_stage duplication`	Unified with batch_size param	[ ]
`torch.load security note`	Comment added acknowledging tradeoff	[ ]
`session.py untested`	README note added	[ ]

---

3. Item 1 — DenseModel Rebuild on Every Ingest

Priority: CRITICAL. At TinyStories scale (100k chunks), re-encoding all accumulated chunks on every ingest stage produces quadratic total encoding cost and will make the system unusable.

Acceptance Criteria

- DenseModel.__init__() encodes all initial chunks exactly once using batch encoding with device='cuda' and batch_size=512
- A separate add_chunks() method exists that encodes only new chunks and appends them to self.embeddings using np.vstack() or equivalent
- No call to model.encode() exists anywhere in DenseModel.query()
- No call to model.encode() exists anywhere that receives the full accumulated chunk list after initialization

Edge Case to Verify

After three ingest stages adding 10 chunks each, self.embeddings should contain exactly 30 rows — not 10, not 30 re-encoded from scratch on the third call. Trace the embedding count through three sequential add_chunks() calls and confirm it accumulates correctly.

Secondary Risk

Confirm that self.labels accumulates correctly in parallel with self.embeddings. A mismatch between embedding count and label count will cause silent wrong routing results without raising an error.

---

4. Item 2 — assign_slot O(n) Dormant Slot Scan

Priority: CRITICAL. Scanning all 200k dormant slots on every chunk assignment produces 200k x 384 matrix operations per chunk. At TinyStories scale this runs on CPU and will be the primary bottleneck.

Acceptance Criteria

- VectorSpace.__init__() initializes self.dormant_queue as a list or deque containing all slot indices from 0 to n_slots-1
- assign_slot() uses self.dormant_queue.pop(0) or deque.popleft() to claim the next available slot in O(1)
- No matrix scan or cosine similarity computation exists in assign_slot() for the purpose of finding a dormant slot

Critical Edge Case — Pruning Must Return Slots to Queue

This is the most likely secondary bug introduced by the fix. When prune() zeroes out slots below the activation threshold, those slots become dormant again. They MUST be returned to dormant_queue or the queue will eventually empty and slot assignment will fail.

```
def prune(self, threshold: float):
    with self._lock:
        pruned = []
        for idx in list(self.slot_labels.keys()):
            if self.activation[idx] < threshold:
                # Zero out slot
                self.slots[idx] = torch.zeros(self.dimensions)
                self.activation[idx] = 0.0
                del self.slot_labels[idx]
                self.n_active -= 1
                # CRITICAL — return to dormant queue
                self.dormant_queue.append(idx)
                pruned.append(idx)
        return pruned
```

Verify that the prune() method contains the dormant_queue.append(idx) call for every pruned slot. If this is missing, after enough prune/grow cycles the queue will exhaust and the system will crash.

Performance Recommendation

For best performance replace list with collections.deque — popleft() on deque is O(1) while pop(0) on list is O(n). At 200k slots this matters.

```
from collections import deque
self.dormant_queue = deque(range(n_slots))
```

---

5. Item 3 — Thread Safety

Priority: HIGH. Gradio triggers callbacks in separate threads. Concurrent VectorSpace mutations without locking will produce corrupted activation scores, slot_labels dict, and dormant_queue state.

Acceptance Criteria

- VectorSpace.__init__() initializes self._lock = threading.RLock()
- assign_slot() acquires self._lock via with self._lock: wrapping all mutations
- route_query() acquires self._lock for the duration of the similarity search and reinforcement update
- prune() acquires self._lock for the entire pruning pass
- decay() acquires self._lock if implemented

Critical Deadlock Check

RLock is reentrant — the same thread can acquire it multiple times without deadlocking. However verify that no method holding the lock calls another external function that tries to acquire a different non-reentrant lock. This would cause a deadlock that only surfaces under concurrent load and is extremely difficult to debug.

Specific Pattern to Check

Verify that route_query() does not call assign_slot() or any other method that also acquires self._lock while already inside a with self._lock: block. If reinforcement logic inside route_query() calls assign_slot() this will deadlock with a standard Lock but not with RLock. Confirm RLock is used, not Lock.

---

6. Item 4 — Boundary Violation Heuristic

Priority: HIGH. The string check 'negative' in nearest_domain is fragile. A domain named 'non-negative-math' or 'negative-space-art' would incorrectly trigger a boundary violation verdict.

Acceptance Criteria

- VectorSpace contains a self.negative_domains = set() registry initialized in __init__()
- A register_negative_domain(label) method exists that adds a domain label to self.negative_domains
- This method is called whenever a domain label containing 'negative' is ingested — or the user explicitly registers a domain as negative
- The verdict logic in comparison_harness.py uses nearest_domain in vector_space.negative_domains rather than 'negative' in nearest_domain

Critical Edge Case — Persistence

This is the most likely silent failure in the entire codebase after fixes are applied. If self.negative_domains is not included in the .bgstate save state, every time the network is loaded from disk the negative_domains set will be empty and boundary violation detection will silently stop working.

Verify that vector_space.py save() includes negative_domains in the state dict:

```
state = {
    'slots':           self.slots,
    'activation':      self.activation,
    'slot_labels':     self.slot_labels,
    'n_active':        self.n_active,
    'stage_number':    self.stage_number,
    'domain_registry': self.domain_registry,
    'negative_domains': self.negative_domains,  # MUST BE HERE
    'metadata':        { ... }
}
```

And that load() restores it:

```
vs.negative_domains = state.get('negative_domains', set())
```

The .get() with default empty set ensures backward compatibility with .bgstate files saved before this fix was applied.

---

7. Item 5 — ingest_stage / ingest_stage_batched Duplication

Priority: MEDIUM. Two nearly identical code paths sharing helpers increases maintenance burden and creates risk of fixes applied to one path not being applied to the other.

Acceptance Criteria

- A single ingest_stage() method exists with a batch_size parameter defaulting to 1
- When batch_size == 1 the method processes chunks individually
- When batch_size > 1 the method uses batched GPU encoding
- Both paths call the same slot assignment, activation, and autosave logic — no duplication
- ingest_stage_batched() has been removed or marked as deprecated

Verification

Confirm the unified method produces identical slot assignment results for identical input regardless of batch_size. A quick smoke test: ingest 10 chunks with batch_size=1, reset, ingest the same 10 chunks with batch_size=10, confirm n_active is 10 in both cases and slot_labels contains the same labels.

---

8. Item 6 — torch.load Security Note

Priority: LOW. weights_only=False disables PyTorch's security sandboxing for pickle deserialization. This is necessary to load metadata dicts but should be documented.

Acceptance Criteria

- The torch.load() call in vector_space.py includes weights_only=False
- A comment immediately above the call explains why weights_only=False is required and notes the security implication

Acceptable Comment Format

```
# weights_only=False required to deserialize metadata dicts
# and non-tensor state (slot_labels, domain_registry, etc.)
# Safe for .bgstate files created by this system on this machine.
# Do not load .bgstate files received from untrusted external sources.
state = torch.load(path, map_location='cpu', weights_only=False)
```

---

9. Item 7 — session.py Untested

Priority: LOW. session.py is the orchestration layer connecting all modules. Integration bugs would only surface at runtime. Not blocking for research POC use but should be documented.

Acceptance Criteria

- README.md contains a note that session.py has not been covered by automated tests
- The note advises that integration testing should be performed before any production deployment
- Alternatively — basic smoke tests exist for session.py covering at minimum: initialization, single ingest stage, single query, single prune pass

Recommended Minimum Smoke Test

```
# tests/test_session_smoke.py
def test_session_smoke():
    from braingrow.vector_space import VectorSpace
    from braingrow.growth_engine import GrowthEngine
    from braingrow.query_router import QueryRouter

    vs = VectorSpace(n_slots=1000, dimensions=384)
    ge = GrowthEngine(vs)
    qr = QueryRouter(vs)

    # Ingest
    ge.ingest_stage([('Test sentence.', 'test')], batch_size=1)
    assert vs.n_active == 1

    # Query
    result = qr.route_query('Test sentence.')
    assert len(result['matches']) > 0

    # Prune
    pruned = vs.prune(threshold=0.99)
    assert vs.n_active == 0
    assert len(vs.dormant_queue) == 1000
```

---

10. Instructions to Copilot

Please perform the following steps in order:

- **1.** Analyze the current codebase against each acceptance criteria section above.
- **2.** For each item report: CONFIRMED (fix correctly implemented), PARTIAL (fix attempted but incomplete or introduces secondary issue), or UNRESOLVED (fix not found or incorrect).

- **3.** For any PARTIAL or UNRESOLVED items provide the specific code location, what was found, and the exact change needed to reach CONFIRMED status.
- **4.** Pay special attention to the two critical edge cases: pruned slots returning to dormant_queue (Item 2) and negative_domains persisted in save/load (Item 4). These are the most likely silent failures.
- **5.** Complete the verification summary table from Section 2 with final status for each item.
- **6.** If all seven items are CONFIRMED, report the codebase as ready for TinyStories Stage B testing.

The goal is not to find more bugs — it is to confirm that the seven known issues have been fully resolved and that the fixes themselves have not introduced secondary problems. A clean CONFIRMED on all seven items means the codebase is ready to scale.
